

4.3 Crosstab (Chi-Square)

Chi-Square Tests

	Value	df	Asymptotic Significance (2- sided)
Pearson Chi-Square	16.889 ^a	4	.002
Likelihood Ratio	17.213	4	.002
Linear-by-Linear Association	7.011	1	.008
N of Valid Cases	100		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 8.12.			

Interpretation:

There is a substantial correlation ($p = 0.002$) between broker type and investment experience, according to the chi-square test. This implies that investors' choice of broker is influenced by their prior market experience. While seasoned investors prefer full-service brokers or a combination of both because they value dependability, trust, and advisory services, novice investors with less than a year of experience are more likely to utilize discount brokers due to their low cost and ease of use. The presence of a linear trend ($p = 0.008$) further supports the idea that broker selection changes systematically as investment experience rises. There was a significant correlation (Pearson $p = 0.018$) between occupation presently and the type of broker employed in the chi-square test.

Chi-Square Tests

	Value	df	Asymptotic Significance (2- sided)
Pearson Chi-Square	15.242 ^a	6	.018
Likelihood Ratio	15.784	6	.015
Linear-by-Linear Association	3.611	1	.057
N of Valid Cases	100		
a. 5 cells (41.7%) have expected count less than 5. The minimum expected count is 2.32.			

Interpretation:

This demonstrates that an investor's choice of broker is influenced by their line of work. While working and self-employed participants selected full-service brokers or a combination of both, demonstrating their need for advisory services and reliability, students opted to utilize discount brokers since they are more economical and novice-friendly. Overall, the test confirms that occupation is a substantial effect in broker choice, despite certain expected numbers falling below

4.4 Regression

Variables Entered/Removed

Model	Variables Entered	Variables Removed	Method
1	Investing experience	.	Enter
a. Dependent Variable: Type of broker used			
b. All requested variables entered.			

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.432 ^a	.187	.179	.531
a. Predictors: (Constant), Investing experience				

Anova

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	6.359	1	6.359	22.544	.000 ^b
	Residual	27.641	98	.282		
	Total	34.000	99			
a. Dependent Variable: Type of broker used						
b. Predictors: (Constant), Investing experience						

Coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	2.369	.131		18.080	.000
	Investing experience	-.306	.064	-.432	-4.748	.000
a. Dependent Variable: Type of broker used						

Interpretation:

The impact of prior investing expertise on broker selection was investigated using regression analysis. With an R^2 of 0.187, the model was significant ($F = 22.544$, $p < 0.05$), indicating that almost 19% of the variation in broker selection may be explained by investing experience. The coefficient of investing experience was negative ($B = -0.306$, $p < 0.05$), indicating that less experienced and younger investors are more likely to choose cheap brokers, whereas more seasoned investors gradually tilt toward full-service brokers or both.
